```
"""
```

This code was originally written for CS 231n at Stanford University (cs231n.stanford.edu). It has been modified in various areas for use in the ECE 239AS class at UCLA. This includes the descriptions of what code to implement as well as some slight potential changes in variable names to be consistent with class nomenclature. We thank Justin Johnson & Serena Yeung for permission to use this code. To see the original version, please visit cs231n.stanford.edu.

```
def affine_forward(x, w, b):
```

```
    """
```

Computes the forward pass for an affine (fully-connected) layer.

*The input x has shape (N, d_1, ..., d_k) and contains a minibatch of N examples, where each example x[i] has shape (d_1, ..., d_k). We will reshape each input into a vector of dimension $D = d_1 * \dots * d_k$, and then transform it to an output vector of dimension M.*

Inputs:

- x: A numpy array containing input data, of shape (N, d_1, ..., d_k)*
- w: A numpy array of weights, of shape (D, M)*
- b: A numpy array of biases, of shape (M,)*

Returns a tuple of:

- out: output, of shape (N, M)*
- cache: (x, w, b)*

```
    """
```

```
def batchnorm_forward(x, gamma, beta, bn_param):
```

```
    """
```

Forward pass for batch normalization.

During training the sample mean and (uncorrected) sample variance are computed from minibatch statistics and used to normalize the incoming data. During training we also keep an exponentially decaying running mean of the mean and variance of each feature, and these averages are used to normalize data at test-time.

At each timestep we update the running averages for mean and variance using an exponential decay based on the momentum parameter:

*running_mean = momentum * running_mean + (1 - momentum) * sample_mean*

*running_var = momentum * running_var + (1 - momentum) * sample_var*

Note that the batch normalization paper suggests a different test-time behavior: they compute sample mean and variance for each feature using a large number of training images rather than using a running average. For this implementation we have chosen to use running averages instead since they do not require an additional estimation step; the torch7 implementation

of batch normalization also uses running averages.

Input:

- x: Data of shape (N, D)*
- gamma: Scale parameter of shape (D,)*
- beta: Shift parameter of shape (D,)*
- bn_param: Dictionary with the following keys:*
 - mode: 'train' or 'test'; required*
 - eps: Constant for numeric stability*
 - momentum: Constant for running mean / variance.*
 - running_mean: Array of shape (D,) giving running mean of features*
 - running_var: Array of shape (D,) giving running variance of features*

Returns a tuple of:

- out: of shape (N, D)*
- cache: A tuple of values needed in the backward pass*
